# Package 'dfms'

April 3, 2023

```
Version 0.2.1
```

Title Dynamic Factor Models

**Description** Efficient estimation of Dynamic Factor Models using the Expectation Maximization (EM) algorithm

or Two-Step (2S) estimation, supporting datasets with missing data. The estimation options follow advances in the

econometric literature: either running the Kalman Filter and Smoother once with initial values from PCA -

2S estimation as in Doz, Giannone and Reichlin (2011) <doi:10.1016/j.jeconom.2011.02.012> - or via iterated

Kalman Filtering and Smoothing until EM convergence -

following Doz, Giannone and Reichlin (2012)

<doi:10.1162/REST\_a\_00225> -

or using the adapted EM algorithm of Banbura and Modugno (2014) <doi:10.1002/jae.2306>, allowing arbitrary patterns of missing data. The implementation makes heavy use of the 'Armadillo' 'C++' library and

the 'collapse' package, providing for particularly speedy estimation. A comprehensive set of methods supports

interpretation and visualization of the model as well as forecasting. Information criteria to choose the number

of factors are also provided - following Bai and Ng (2002) <doi:10.1111/1468-0262.00273>.

## **Description**

Quickly estimate a VAR(p) model using Armadillo's inverse function.

## Usage

```
.VAR(x, p = 1L)
```

## **Arguments**

x data numeric matrix with time series in columns - without missing values.

p positive integer. The lag order of the VAR.

ainv 3

## Value

A list containing matrices Y = x[-(1:p), ], X which contains lags 1 - p of x combined column-wise, A which is the  $np \times n$  transition matrix, where n is the number of series in x, and the VAR residual matrix res = Y - X % % A.

A list with the following elements:

```
Y x[-(1:p), ].

X lags 1 - p of x combined column-wise.

A np \times n transition matrix, where n is the number of series in x.

VAR residual matrix: Y - X *** A.
```

## **Examples**

```
var = .VAR(diff(EuStockMarkets), 3)
str(var)
var$A
rm(var)
```

ainv

Armadillo's Inverse Functions

## Description

Matrix inverse and pseudo-inverse by the Armadillo C++ library.

## Usage

```
ainv(x)
apinv(x)
```

## **Arguments**

x a numeric matrix, must be square for ainv.

## Value

The matrix-inverse or pseudo-inverse.

```
ainv(crossprod(diff(EuStockMarkets)))
```

4 as.data.frame.dfm

as.data.frame.dfm

Extract Factor Estimates in a Data Frame

## **Description**

Extract Factor Estimates in a Data Frame

#### Usage

```
## S3 method for class 'dfm'
as.data.frame(
    x,
    ...,
    method = "all",
    pivot = c("long", "wide.factor", "wide.method", "wide", "t.wide"),
    time = seq_row(x$F_pca),
    stringsAsFactors = TRUE
)
```

#### **Arguments**

make factors from method and factor identifiers. Same as option to as.data.frame.table.

#### Value

A data frame of factor estimates.

```
library(xts)
# Fit DFM with 3 factors and 3 lags in the transition equation
mod = DFM(diff(BM14_M), r = 3, p = 3)

# Taking a single estimate:
print(head(as.data.frame(mod, method = "qml")))
print(head(as.data.frame(mod, method = "qml", pivot = "wide")))
# Adding a proper time variable
```

BM14\_Models 5

```
time = index(BM14_M)[-1L]
print(head(as.data.frame(mod, method = "qml", time = time)))

# All estimates: different pivoting methods
for (pv in c("long", "wide.factor", "wide.method", "wide", "t.wide")) {
   cat("\npivot = ", pv, "\n")
   print(head(as.data.frame(mod, pivot = pv, time = time), 3))
}
```

BM14\_Models

Euro Area Macroeconomic Data from Banbura and Modugno 2014

## **Description**

A data extract from BM 2014 replication files. Some proprietary series (mostly PMI's) are excluded. The dataset BM14\_Models provides information about all series and their inclusion in the 'small', 'medium' and 'large' sized dynamic factor models estimated by BM 2014. The actual data is contained in *xts* format in BM14\_M for monthly data and BM14\_Q for quarterly data.

#### Usage

BM14\_Models BM14\_M BM14\_Q

#### **Format**

BM14\_Models is a data frame with 101 obs. (series) and 8 columns:

series BM14 series code (converted to snake case for R)

label BM14 series label

code original series code from data source

freq series frequency

**log\_trans** logical indicating whether the series was transformed by the natural log before differencing. Note that all data are provided in untransformed levels, and all data was (log-)differenced by BM14 before estimation.

**small** logical indicating series included in the 'small' model of BM14. Proprietary series are excluded.

**medium** logical indicating series included in the 'medium' model of BM14. Proprietary series are excluded.

**large** logical indicating series included in the 'large' model of BM14. This comprises all series, thus the variable is redundant but included for completeness. Proprietary series are excluded.

#### **Source**

Banbura, M., & Modugno, M. (2014). Maximum likelihood estimation of factor models on datasets with arbitrary pattern of missing data. *Journal of Applied Econometrics*, 29(1), 133-160.

## **Examples**

```
library(magrittr)
library(xts)

# Constructing the database for the large model
BM14 = merge(BM14_M, BM14_Q)
BM14[, BM14_Models$log_trans] %<>% log()
BM14[, BM14_Models$freq == "M"] %<>% diff()
BM14[, BM14_Models$freq == "Q"] %<>% diff(3)

# Small Model Database
head(BM14[, BM14_Models$small])

# Medium-Sized Model Database
head(BM14[, BM14_Models$medium])
```

DFM

Estimate a Dynamic Factor Model

## Description

Efficient estimation of a Dynamic Factor Model via the EM Algorithm - on stationary data with time-invariant system matrices and classical assumptions, while permitting missing data.

## Usage

```
DFM(
    X,
    r,
    p = 1L,
    ...,
    idio.ar1 = FALSE,
    rQ = c("none", "diagonal", "identity"),
    rR = c("diagonal", "identity", "none"),
    em.method = c("auto", "DGR", "BM", "none"),
    min.iter = 25L,
    max.iter = 100L,
    tol = 1e-04,
    pos.corr = TRUE,
    check.increased = FALSE
)
```

#### **Arguments**

X	a Tx n numeric data matrix or frame of stationary time series. May contain missing values.
r	integer. number of factors.
р	integer. number of lags in factor VAR.
	(optional) arguments to tsnarmimp.
idio.ar1	logical. Model observation errors as AR(1) processes: $e_t = \rho e_{t-1} + v_t$ . Note that this substantially increases computation time, and is generaly not needed if n is large (>30). See theoretical vignette for details.
rQ	character. restrictions on the state (transition) covariance matrix (Q).
rR	character. restrictions on the observation (measurement) covariance matrix (R).
em.method	character. The implementation of the Expectation Maximization Algorithm used. The options are:

"auto" Automatic selection: "BM" if anyNA(X), else "DGR".

"DGR" The classical EM implementation of Doz, Giannone and Reichlin (2012). This implementation is efficient and qu

"BM" The modified EM algorithm of Banbura and Modugno (2014) which also accounts for missing data in the EM ite

"none" Performs no EM iterations and just returns the Two-Step estimates from running the data through the Kalman Fil

min.iter integer. Minimum number of EM iterations (to ensure a convergence path).

max.iter integer. Maximum number of EM iterations.

tol numeric. EM convergence tolerance.

pos.corr logical. Increase the likelihood that factors correlate positively with the data, by

scaling the eigenvectors such that the principal components (used to initialize the Kalman Filter) co-vary positively with the row-means of the standardized

data.

check.increased

logical. Check if likelihood has increased. Passed to em\_converged. If TRUE, the algorithm only terminates if convergence was reached with decreasing likelihood.

#### Details

This function efficiently estimates a Dynamic Factor Model with the following classical assumptions:

- 1. Linearity
- 2. Idiosynchratic measurement (observation) errors (R is diagonal)
- 3. No direct relationship between series and lagged factors (*ceteris paribus* contemporaneous factors)

4. No relationship between lagged error terms in the either measurement or transition equation (no serial correlation), unless explicitly modeled as AR(1) processes using idio.ar1 = TRUE.

Factors are allowed to evolve in a VAR(p) process, and data is internally standardized (scaled and centered) before estimation (removing the need of intercept terms). By assumptions 1-4, this translates into the following dynamic form:

$$\mathbf{x}_t = \mathbf{C}_0 \mathbf{f}_t + \mathbf{e}_t \sim N(\mathbf{0}, \mathbf{R})$$

$$\mathbf{f}_t = \sum_{j=1}^p \mathbf{A}_j \mathbf{f}_{t-j} + \mathbf{u}_t \sim N(\mathbf{0}, \mathbf{Q}_0)$$

where the first equation is called the measurement or observation equation and the second equation is called transition, state or process equation, and

number of series in  $\mathbf{x}_t$  (r and p as the arguments to DFM).

 $\mathbf{x}_t$   $n \times 1$  vector of observed series at time  $t: (x_{1t}, \dots, x_{nt})'$ . Some observations can be missing.

 $\mathbf{f}_t$   $r \times 1$  vector of factors at time  $t: (f_{1t}, \dots, f_{rt})'$ .

 $\mathbf{C}_0$   $n \times r$  measurement (observation) matrix.

 $\mathbf{A}_i$   $r \times r$  state transition matrix at lag j.

 $\mathbf{Q}_0$   $r \times r$  state covariance matrix.

 $\mathbf{R}$   $n \times n$  measurement (observation) covariance matrix. It is diagonal by assumption 2 that  $E[\mathbf{x}_{it}|\mathbf{x}_{-i,t},\mathbf{x}_{i,t-1},\ldots,\mathbf{f}_t,\mathbf{f}_t]$ 

This model can be estimated using a classical form of the Kalman Filter and the Expectation Maximization (EM) algorithm, after transforming it to State-Space (stacked, VAR(1)) form:

$$\mathbf{x}_t = \mathbf{C}\mathbf{F}_t + \mathbf{e}_t \sim N(\mathbf{0}, \mathbf{R})$$

$$\mathbf{F}_t = \mathbf{A} \, \mathbf{F}_{t-1} + \mathbf{u}_t \sim N(\mathbf{0}, \mathbf{O})$$

where

number of series in  $\mathbf{x}_t$  (r and p as the arguments to DFM).

 $\mathbf{x}_t$   $n \times 1$  vector of observed series at time  $t: (x_{1t}, \dots, x_{nt})'$ . Some observations can be missing.

 $\mathbf{F}_t$   $rp \times 1$  vector of stacked factors at time t:  $(f_{1t}, \dots, f_{rt}, f_{1,t-1}, \dots, f_{r,t-1}, \dots, f_{1,t-p}, \dots, f_{r,t-p})'$ .

 $\mathbf{C}$   $n \times rp$  observation matrix. Only the first  $n \times r$  terms are non-zero, by assumption 3 that  $E[\mathbf{x}_t|\mathbf{F}_t] = E[\mathbf{x}_t|\mathbf{f}_t]$  (no relative to the first  $n \times r$  terms are non-zero, by assumption 3 that  $E[\mathbf{x}_t|\mathbf{F}_t] = E[\mathbf{x}_t|\mathbf{f}_t]$ 

A stacked  $rp \times rp$  state transition matrix consisting of 3 parts: the top  $r \times rp$  part provides the dynamic relationships ca

 $\mathbf{Q} = rp \times rp$  state covariance matrix. The top  $r \times r$  part gives the contemporaneous relationships, the rest are zeros by assistance matrix.

 $\mathbf{R}$   $n \times n$  observation covariance matrix. It is diagonal by assumption 2 and identical to  $\mathbf{R}$  as stated in the dynamic form.

#### Value

A list-like object of class 'dfm' with the following elements:

X_imp	$T \times n$ matrix with the imputed and standardized (scaled and centered) data -

with attributes attached allowing reconstruction of the original data:

"stats" is a  $n \times 5$  matrix of summary statistics of class "qsu" (see qsu).

"missing" is a  $T \times n$  logical matrix indicating missing or infinite values in the original data (which are imputed in X

"attributes" contains the attributes of the original data input.

"is.list" is a logical value indicating whether the original data input was a list / data frame.

eigen  $eigen(cov(X_imp))$ .

F\_pca  $T \times r$  matrix of principal component factor estimates - X\_imp %\*% eigen\$vectors.

P\_0  $r \times r$  initial factor covariance matrix estimate based on PCA results.

 $F_2$ s  $T \times r$  matrix two-step factor estimates as in Doz, Giannone and Reichlin (2011)

- obtained from running the data through the Kalman Filter and Smoother once,

where the Filter is initialized with results from PCA.

P\_2s  $r \times r \times T$  covariance matrices of two-step factor estimates.

 $F_{\text{qml}}$   $T \times r$  matrix of quasi-maximum likelihood factor estimates - obtained by iter-

atively Kalman Filtering and Smoothing the factor estimates until EM conver-

gence.

P\_qml  $r \times r \times T$  covariance matrices of QML factor estimates.

A  $r \times rp$  factor transition matrix.

C  $n \times r$  observation matrix.

Q  $r \times r$  state (error) covariance matrix.

R  $n \times n$  observation (error) covariance matrix.

e  $T \times n$  estimates of observation errors  $\mathbf{e}_t$ . Only available if idio.ar1 = TRUE.

rho  $n \times 1$  estimates of AR(1) coefficients ( $\rho$ ) in observation errors:  $e_t = \rho e_{t-1} + v_t$ .

Only available if idio.ar1 = TRUE.

loglik vector of log-likelihoods - one for each EM iteration. The final value corre-

sponds to the log-likelihood of the reported model.

The numeric convergence tolerance used.

converged single logical valued indicating whether the EM algorithm converged (within max.iter iterations subject to tol).

anyNA single logical valued indicating whether there were any (internal) missing values in the data (determined after removal of rows with too many missing values). If FALSE, X\_imp is simply the original data in matrix form, and does not have the "missing" attribute attached.

rm.rows vector of any cases (rows) that were removed beforehand (subject to max.missing and na.rm.method). If no cases were removed the slot is NULL.

em.method The EM method used.

call object obtained from match.call().

Convergence Test for EM-Algorithm

## Description

Convergence Test for EM-Algorithm

## Usage

```
em_converged(loglik, previous_loglik, tol = 1e-04, check.increased = FALSE)
```

## Arguments

```
\label{loglik} \begin{tabular}{ll} loglik & numeric. Current value of the log-likelihood function. \\ previous_loglik & numeric. Value of the log-likelihood function at the previous iteration. \\ tol & numerical. The tolerance of the test. If $|LL(t) - LL(t-1)| / avg < tol, where avg = $(|LL(t)| + |LL(t-1)|)/2$, then algorithm has converged. \\ check.increased & logical. Check if likelihood has increased. \\ \end{tabular}
```

#### Value

A logical statement indicating whether EM algorithm has converged. if check.increased = TRUE, a vector with 2 elements indicating the convergence status and whether the likelihood has decreased.

```
em_converged(1001, 1000)
em_converged(10001, 10000)
em_converged(10001, 10000, check = TRUE)
em_converged(10000, 10001, check = TRUE)
```

FIS

(Fast) Fixed-Interval Smoother (Kalman Smoother)

13

FIS

## **Description**

(Fast) Fixed-Interval Smoother (Kalman Smoother)

#### Usage

```
FIS(A, F, F_pred, P, P_pred, F_0 = NULL, P_0 = NULL)
```

## **Arguments**

A	transition matrix $(rp \times rp)$ .
F	state estimates $(T \times rp)$ .
F_pred	state predicted estimates $(T \times rp)$ .
Р	variance estimates $(rp \times rp \times T)$ .
P_pred	predicted variance estimates $(rp \times rp \times T)$ .
F_0	initial state vector $(rp \times 1)$ or empty (NULL).
P_0	initial state covariance $(rp \times rp)$ or empty (NULL).

#### **Details**

The Kalman Smoother is given by:

$$\begin{split} \mathbf{J}_t &= \mathbf{P}_t \mathbf{A} + inv(\mathbf{P}^{pred}_{t+1}) \\ \mathbf{F}^{smooth}_t &= \mathbf{F}_t + \mathbf{J}_t(\mathbf{F}^{smooth}_{t+1} - \mathbf{F}^{pred}_{t+1}) \\ \mathbf{P}^{smooth}_t &= \mathbf{P}_t + \mathbf{J}_t(\mathbf{P}^{smooth}_{t+1} - \mathbf{P}^{pred}_{t+1}) \mathbf{J}_t' \end{split}$$

The initial smoothed values for period t = T are set equal to the filtered values. If  $F_0$  and  $P_0$  are supplied, the smoothed initial conditions (t = 0 values) are also calculated and returned. For further details see any textbook on time series such as Shumway & Stoffer (2017), which provide an analogous R implementation in astsa::Ksmooth0.

## Value

Smoothed state and covariance estimates, including initial (t = 0) values.

F_smooth	$T \times rp$ smoothed state vectors, equal to the filtered state in period $T$ .
P_smooth	$rp\times rp\times T$ smoothed state covariance, equal to the filtered covariance in period $T.$
F_smooth_0	$1 \times rp$ initial smoothed state vectors, based on F_0.
P_smooth_0	$rp \times rp$ initial smoothed state covariance, based on P_0.

ICr

*Information Criteria to Determine the Number of Factors (r)* 

## **Description**

Minimizes 3 information criteria proposed by Bai and Ng (2002) to determine the optimal number of factors  $r^*$  to be used in an approximate factor model. A Screeplot can also be computed to eyeball the number of factors in the spirit of Onatski (2010).

#### Usage

```
ICr(X, max.r = min(20, ncol(X) - 1))
## S3 method for class 'ICr'
print(x, ...)
## S3 method for class 'ICr'
plot(x, ...)
## S3 method for class 'ICr'
screeplot(x, type = "pve", show.grid = TRUE, max.r = 30, ...)
```

## **Arguments**

X	a T x n numeric data matrix or frame of stationary time series.
max.r	integer. The maximum number of factors for which IC should be computed (or eigenvalues to be displayed in the screeplot).
x	an object of type 'ICr'.
	further arguments to ts.plot or plot.
type	character. Either "ev" (eigenvalues), "pve" (percent variance explained), or "cum.pve" (cumulative PVE). Multiple plots can be requested.
show.grid	logical. TRUE shows gridlines in each plot.

ICr 15

#### **Details**

Following Bai and Ng (2002) and De Valk et al. (2019), let NSSR(r) be the normalized sum of squared residuals  $SSR(r)/(n \times T)$  when r factors are estimated using principal components. Then the information criteria can be written as follows:

$$IC_{r1} = \ln(NSSR(r)) + r\left(\frac{n+T}{nT}\right) + \ln\left(\frac{nT}{n+T}\right)$$

$$IC_{r2} = \ln(NSSR(r)) + r\left(\frac{n+T}{nT}\right) + \ln(\min(n,T))$$

$$IC_{r3} = \ln(NSSR(r)) + r\left(\frac{\ln(\min(n,T))}{\min(n,T)}\right)$$

The optimal number of factors  $r^*$  corresponds to the minimum IC. The three criteria are are asymptotically equivalent, but may give significantly different results for finite samples. The penalty in  $IC_{r2}$  is highest in finite samples.

In the Screeplot a horizontal dashed line is shown signifying an eigenvalue of 1, or a share of variance corresponding to 1 divided by the number of eigenvalues.

#### Value

A list of 4 elements:

F\_pca T x n matrix of principle component factor estimates.

eigenvalues the eigenvalues of the covariance matrix of X.

IC r.max x 3 'table' containing the 3 information criteria of Bai and Ng (2002),

computed for all values of r from 1:r.max.

r.star vector of length 3 containing the number of factors (r) minimizing each infor-

mation criterion.

#### Note

To determine the number of lags (p) in the factor transition equation, use the function vars::VARselect with  $r^*$  principle components (also returned by ICr).

## **Arguments**

x an object class 'dfm'.

method character. The factor estimates to use: one of "qml", "2s", "pca" or "all" to

plot all estimates.

type character. The type of plot: "joint", "individual" or "residual".

scale.factors logical. Standardize factor estimates, this usually improves the plot since the

factor estimates corresponding to the greatest PCA eigenvalues tend to have a

greater variance than the data.

 $\dots \qquad \qquad \text{for plot.dfm: further arguments to plot, ts.plot, or boxplot, depending on} \\$ 

the type of plot. For screeplot.dfm: further arguments to screeplot.ICr.

predict.dfm 17

#### Value

Nothing.

## **Examples**

```
# Fit DFM with 3 factors and 3 lags in the transition equation
mod = DFM(diff(BM14_M), r = 3, p = 3)
plot(mod)
plot(mod, type = "individual", method = "all")
plot(mod, type = "residual")
```

predict.dfm

**DFM Forecasts** 

#### **Description**

This function produces h-step ahead forecasts of both the factors and the data, with an option to also forecast autocorrelated residuals with a univariate method and produce a combined forecast.

## Usage

```
## S3 method for class 'dfm'
predict(
  object,
 h = 10L,
 method = switch(object$em.method, none = "2s", "qml"),
  standardized = TRUE,
  resFUN = NULL,
  resAC = 0.1,
)
## S3 method for class 'dfm_forecast'
print(x, digits = 4L, ...)
## S3 method for class 'dfm_forecast'
plot(
 main = paste(x$h, "Period Ahead DFM Forecast"),
  xlab = "Time",
 ylab = "Standardized Data",
  factors = seq_len(ncol(x$F)),
  scale.factors = TRUE,
  factor.col = rainbow(length(factors)),
```

18 predict.dfm

```
factor.lwd = 1.5,
  fcst.lty = "dashed",
  data.col = c("grey85", "grey65"),
  legend = TRUE,
  legend.items = paste0("f", factors),
  grid = FALSE,
  vline = TRUE,
  vline.lty = "dotted",
  vline.col = "black",
)
## S3 method for class 'dfm_forecast'
as.data.frame(
 Х,
  . . . ,
  use = c("factors", "data", "both"),
 pivot = c("long", "wide"),
 time = seq_len(nrow(x$F) + x$h),
  stringsAsFactors = TRUE
)
```

#### **Arguments**

object an object of class 'dfm'.

h integer. The forecast horizon.

method character. The factor estimates to use: one of "qml", "2s" or "pca".

standardized logical. FALSE will return data forecasts on the original scale.

resFUN an (optional) function to compute a univariate forecast of the residuals. The

function needs to have a second argument providing the forecast horizon (h) and

return a vector or forecasts. See Examples.

resAC numeric. Threshold for residual autocorrelation to apply resFUN: only residual

series where AC1 > resAC will be forecasted.

... not used.

x an object class 'dfm\_forecast'.

digits integer. The number of digits to print out.

main, xlab, ylab

character. Graphical parameters passed to ts.plot.

factors integers indicating which factors to display. Setting this to NA, NULL or 0 will

omit factor plots.

scale.factors logical. Standardize factor estimates, this usually improves the plot since the

factor estimates corresponding to the greatest PCA eigenvalues tend to have a

greater variance than the data.

factor.col, factor.lwd

graphical parameters affecting the colour and line width of factor estimates plots. See par.

predict.dfm 19

fcst.1ty integer or character giving the line type of the forecasts of factors and data. See

par.

data.col character vector of length 2 indicating the colours of historical data and forecasts

of that data. Setting this to NA, NULL or "" will not plot data and data forecasts.

legend logical. TRUE draws a legend in the top-left of the chart.

legend.items character names of factors for the legend.

grid logical. TRUE draws a grid on the background of the plot.

vline logical. TRUE draws a vertical line deliminating historical data and forecasts.

vline.lty, vline.col

graphical parameters affecting the appearance of the vertical line. See par.

use character. Which forecasts to use "factors", "data" or "both".

pivot character. The orientation of the frame: "long" or "wide".

time a vector identifying the time dimension, must be of length T + h, or NULL to omit

a time variable.

stringsAsFactors

logical. If TRUE and pivot = "long" the 'Variable' column is created as a factor.

Same as option to as.data.frame.table.

#### Value

A list-like object of class 'dfm\_forecast' with the following elements:

X\_fcst  $h \times n$  matrix with the forecasts of the variables.

F\_fcst  $h \times r$  matrix with the factor forecasts.

X  $T \times n$  matrix with the standardized (scaled and centered) data - with attributes

attached allowing reconstruction of the original data:

"stats" is a  $n \times 5$  matrix of summary statistics of class "qsu" (see qsu). Only attached if standardized = TRUE.

"attributes" contains the attributes of the original data input.

"is.list" is a logical value indicating whether the original data input was a list / data frame.

F  $T \times r$  matrix of factor estimates. method the factor estimation method used.

anyNA logical indicating whether X contains any missing values.

h the forecast horizon.

resid.fc logical indicating whether a univariate forecasting function was applied to the

residuals.

resid.fc.ind indices indicating for which variables (columns of X) the residuals were fore-

casted using the univariate function.

call object obtained from match.call().

20 residuals.dfm

### **Examples**

```
library(xts)
library(collapse)
# Fit DFM with 3 factors and 3 lags in the transition equation
mod = DFM(diff(BM14_M), r = 3, p = 3)
# 15 period ahead forecast
fc = predict(mod, h = 15)
print(fc)
plot(fc, xlim = c(300, 370))
# Also forecasting autocorrelated residuals with an AR(1)
fcfun <- function(x, h) predict(ar(na_rm(x)), n.ahead = h)pred
fcar = predict(mod, resFUN = fcfun, h = 15)
plot(fcar, xlim = c(300, 370))
# Retrieving a data frame of the forecasts
head(as.data.frame(fcar, pivot = "wide")) # Factors
head(as.data.frame(fcar, use = "data"))  # Data
head(as.data.frame(fcar, use = "both"))  # Both
```

residuals.dfm

DFM Residuals and Fitted Values

## Description

The residuals  $\mathbf{e}_t = \mathbf{x}_t - \mathbf{C}\mathbf{F}_t$  or fitted values  $\mathbf{C}\mathbf{F}_t$  of the DFM observation equation.

## Usage

```
## S3 method for class 'dfm'
residuals(
  object,
  method = switch(object$em.method, none = "2s", "qml"),
  orig.format = FALSE,
  standardized = FALSE,
  na.keep = TRUE,
  ...
)

## S3 method for class 'dfm'
fitted(
  object,
  method = switch(object$em.method, none = "2s", "qml"),
  orig.format = FALSE,
```

SKF 21

```
standardized = FALSE,
na.keep = TRUE,
...
)
```

#### **Arguments**

object an object of class 'dfm'.

method character. The factor estimates to use: one of "qml", "2s" or "pca".

orig.format logical. TRUE returns residuals/fitted values in a data format similar to X.

standardized logical. FALSE will put residuals/fitted values on the original data scale.

na.keep logical. TRUE inserts missing values where X is missing (default TRUE as resid-

uals/fitted values are only defined for observed data). FALSE returns the raw prediction, which can be used to interpolate data based on the DFM. For residuals, FALSE returns the difference between the prediction and the initial imputed

version of X use for PCA to initialize the Kalman Filter.

. . . not used.

#### Value

A matrix of DFM residuals or fitted values. If orig. format = TRUE the format may be different, e.g. a data frame.

## Examples

```
library(xts)
# Fit DFM with 3 factors and 3 lags in the transition equation
mod = DFM(diff(BM14_M), r = 3, p = 3)

# Residuals
head(resid(mod))
plot(resid(mod, orig.format = TRUE)) # this is an xts object

# Fitted values
head(fitted(mod))
head(fitted(mod, orig.format = TRUE)) # this is an xts object
```

SKF

(Fast) Stationary Kalman Filter

#### **Description**

A simple and fast C++ implementation of the Kalman Filter for stationary data with time-invariant system matrices and missing data.

22 SKF

#### Usage

$$SKF(X, A, C, Q, R, F_0, P_0, loglik = FALSE)$$

#### **Arguments**

Χ	numeric data matrix $(T \times n)$ .
A	transition matrix $(rp \times rp)$ .
С	observation matrix $(n \times rp)$ .
Q	state covariance $(rp \times rp)$ .
R	observation covariance $(n \times n)$ .
F_0	initial state vector $(rp \times 1)$ .
P_0	initial state covariance $(rp \times rp)$ .
loglik	logical. Compute log-likelihood?

#### **Details**

The underlying state space model is:

$$\mathbf{x}_t = \mathbf{C}\mathbf{F}_t + \mathbf{e}_t \sim N(\mathbf{0}, \mathbf{R})$$
$$\mathbf{F}_t = \mathbf{A} \mathbf{F}_{t-1} + \mathbf{u}_t \sim N(\mathbf{0}, \mathbf{Q})$$

where  $x_t$  is X[t, ]. The filter then first performs a time update (prediction)

$$\mathbf{F}_t = \mathbf{A} \ \mathbf{F}_{t-1}$$
 
$$\mathbf{P}_t = \mathbf{A} \ \mathbf{P}_{t-1} \mathbf{A}' + \mathbf{Q}$$

where  $P_t = Cov(F_t)$ . This is followed by the measurement update (filtering)

$$\mathbf{K}_t = \mathbf{P}_t \mathbf{C}' (\mathbf{C} \, \mathbf{P}_t \mathbf{C}' + \mathbf{R})^{-1}$$

$$\mathbf{F}_t = \mathbf{F}_t + \mathbf{K}_t (\mathbf{x}_t - \mathbf{C} \, \mathbf{F}_t)$$

$$\mathbf{P}_t = \mathbf{P}_t - \mathbf{K}_t \mathbf{C} \, \mathbf{P}_t$$

If a row of the data is all missing the measurement update is skipped i.e. the prediction becomes the filtered value. The log-likelihood is computed as

$$1/2 \sum_{t} \log(|St|) - e'_{t} S_{t} e_{t} - n \log(2\pi)$$

where  $S_t = (CP_tC' + R)^{-1}$  and  $e_t = x_t - CF_t$  is the prediction error.

For further details see any textbook on time series such as Shumway & Stoffer (2017), which provide an analogous R implementation in astsa::Kfilter0. For another fast (C-based) implementation that also allows time-varying system matrices and non-stationary data see FKF::fkf.

SKFS 23

#### Value

Predicted and filtered state vectors and covariances.

F  $T \times rp$  filtered state vectors.

P  $rp \times rp \times T$  filtered state covariances.

F\_pred  $T \times rp$  predicted state vectors.

P\_pred  $rp \times rp \times T$  predicted state covariances.

loglik value of the log likelihood.

SKFS

(Fast) Stationary Kalman Filter and Smoother

## **Description**

(Fast) Stationary Kalman Filter and Smoother

## Usage

```
SKFS(X, A, C, Q, R, F_0, P_0, loglik = FALSE)
```

## Arguments

Χ	numeric data matrix $(T \times n)$ .
A	transition matrix $(rp \times rp)$ .
С	observation matrix $(n \times rp)$ .
Q	state covariance $(rp \times rp)$ .
R	observation covariance $(n \times n)$ .
F_0	initial state vector $(rp \times 1)$ .
P_0	initial state covariance $(rp \times rp)$ .
loglik	logical. Compute log-likelihood?

24 SKFS

#### Value

All results from SKF and FIS, and additionally a  $rp \times rp \times T$  matrix PPm\_smooth, which is equal to the estimate of  $Cov(F^smooth_t, F^smooth_{t-1}|T)$  and needed for EM iterations. See 'Property 6.3: The Lag-One Covariance Smoother' in Shumway & Stoffer (2017).

summary.dfm

DFM Summary Methods

## **Description**

Summary and print methods for class 'dfm'. print.dfm just prints basic model information and the factor transition matrix  $\mathbf{A}$ , summary.dfm returns all system matrices and additional residual and goodness of fit statistics - with a print method allowing full or compact printout.

## Usage

```
## S3 method for class 'dfm'
print(x, digits = 4L, ...)
## S3 method for class 'dfm'
summary(object, method = switch(object$em.method, none = "2s", "qml"), ...)
## S3 method for class 'dfm_summary'
print(x, digits = 4L, compact = sum(x$info["n"] > 15, x$info["n"] > 40), ...)
```

#### **Arguments**

x, object an object class 'dfm'.

digits integer. The number of digits to print out.

... not used.

method character. The factor estimates to use: one of "qml", "2s" or "pca".

compact integer. Display a more compact printout: 0 prints everything, 1 omits the observation matrix C and residual covariance matrix cov(resid(model)), and 2 omits all disaggregated information on the input data. Sensible default are chosen for different sizes of the input dataset so as to limit large printouts.

#### Value

Summary information following a dynamic factor model estimation.

```
mod = DFM(diff(BM14_Q), 2, 3)
print(mod)
summary(mod)
```

26 tsnarmimp

tsnarmimp	Remove and Impute Missing Values in a Multivariate Time Series
tonai ilitilip	Remove and Impute Missing values in a Mutitvariate Time Series

Description

This function imputes missing values in a stationary multivariate time series using various methods, and removes cases with too many missing values.

#### Usage

```
tsnarmimp(
   X,
   max.missing = 0.8,
   na.rm.method = c("LE", "all"),
   na.impute = c("median.ma.spline", "median.ma", "median", "rnorm"),
   ma.terms = 3L
)
```

# Arguments X

	time series.
max.missing	numeric. Proportion of series missing for a case to be considered missing.
na.rm.method	character. Method to apply concerning missing cases selected through max.missing: "LE" only removes cases at the beginning or end of the sample, whereas "all" always removes missing cases.
na.impute	character. Method to impute missing values for the PCA estimates used to initialize the EM algorithm. Note that data are standardized (scaled and centered) beforehand. Available options are:
"median"	simple series-wise median imputation.
"rnorm"	imputation with random numbers drawn from a standard normal distribution.
"median.ma"	values are initially imputed with the median, but then a moving average is applied to smooth the e
"median.ma.spline	"internal" missing values (not at the beginning or end of the sample) are imputed using a cubic spl

the order of the (2-sided) moving average applied in na. impute methods "median.ma"

a T x n numeric data matrix (incl. ts or xts objects) or data frame of stationary

## Value

ma.terms

The imputed matrix X\_imp, with attributes:

and "median.ma.spline".

tsnarmimp 27

"missing" a missingness matrix W matching the dimensions of  $X_{imp}$ .

"rm.rows" and a vector of indices of rows (cases) with too many missing values that were

removed.

```
library(xts)
